An Introduction to Propensity Score Matching
Abstract The use of propensity scores as a method to promote causality in studies that cannot use random assignment has increased dramatically since its original publication in 1983. While the...
A Practical Guide to Getting Started with Propensity Scores
High-dimensional propensity score analysis automatically selects independent variables for calculating propensity scores, using a vast amount of information from real-world health care databases. This technique can reduce confound - ing by indication or unmeasured confounders more precisely compared with conventional propensity score analysis. High-dimensional propensity score analysis assumes that proxy information for important unmeasured confounders

A Practical Introduction to Propensity Score Analysis using R
A propensity score is simply a probability – a number rangingfrom 0 to 1. A propensity score is the probability that a subject will be assigned to a condition or group, based on conditions that exist at the time of the group assignment. The basic SAS syntax to generate propensity scores using PROC LOGISTIC is given below:
Concepts and Issues - Duke University
Propensity score analysis (PSA) arose as a way to achieve exchangeability between exposed and unexposed groups in observational studies without relying on traditional model building. Exchangeability is critical to our causal inference. In experimental studies (e.g. randomized control trials), the probability of being exposed is 0.5.
An Introduction to Propensity Score Analysis
The propensity score is defined as the probability of being exposed given the values of measured confounding variables.3This can be estimated for each individual by fitting, for example, a logistic regression model where the exposure takes the place of the outcome variable, and the measured confounding variables are included as explanatory variables.

The propensity score is a balancing mechanism that works to create groups of subjects which have a similar distribution on background covariates. Matching, stratification, inverse propensity treatment weighting and regression adjustment are all strategies that can be used with the propensity score to create balance between groups of subjects.

Overview. Propensity score analysis (also known as “ matching ”) is a popular way to estimate the effects of programs and policies on outcomes. Yet researchers face a dizzying array of choices, in terms of particular matching techniques to use, as well as many different options for implementing a specific technique.
Gentle Hands-on Introduction to Propensity Score Matching
The propensity score measures the probability of a subject to be in treatment group, and it is calculated using the potential confounding variables. If the distribution of the propensity scores are similar between treatment and placebo, we can say that the confounding factors are averaged out.
Introduction To Propensity Score Analysis
A propensity score is the conditional probability that a subject receives “ treatment ” given t he subject ’ s observed covariates.

The propensity score is a balancing mechanism that works to create groups of subjects which have a similar distribution on background covariates. Matching, stratification, inverse propensity treatment weighting and regression adjustment are all strategies that can be used with the propensity score to create balance between groups of subjects.

Propensity score analysis is a relatively recent statistical innovation that is useful in the analysis of data from quasi-experiments. The goal of propensity score analysis is to balance two non-equivalent groups on observed covariates to get more accurate estimates of the effects of a treatment on which the two groups differ.
