Answer: the number of bridges. Euler proved the number of bridges must be an even number, for example, six bridges instead of seven, if you want to walk over each bridge once and travel to each part

of Königsberg. The solution views each bridge as an endpoint, a vertex in mathematical terms, and the connections between each bridge (vertex).

How many possible ways to cross the bridges at once, if we know the problem has a solution? (Problem relating to Combinatorics) (Problem relating to Combinatorics) In a nutshell, Euler's work on this problem showed us some understanding of the primitive phase of Topology and Graph Theory.

There are five bridges that lead to A, so it needs to be used three times in the eight-letter solution he's looking for. B, C, and D all have two bridges that lead to them, so they each need to appear twice. But $3 + 2 + 2 + 2$ is 9, not 8, even though you must land on only eight landmasses for seven bridges.
