Molecule Polarity - Polarity | Electronegativity | Bonds ... electronegativity values of the atoms present and the overall geometry of the molecule.

This question is reversed in terms of the correct cause and effect relationships. Polarity of the molecule is driven by electronegativity, with the oxygen in water as a prime example.

8.4: Bond Polarity and Electronegativity - Chemistry ...

The amount of energy released when an electron is added to a neutral atom or molecule to form a negative ion. Generally, nonmetals have more positive electron affinity than metals. Chlorine most strongly attracts extra electrons; mercury most weakly attracts an extra electron.

As to the polarity, a molecule is either polar or non-polar, based on the difference in the

the polarity of a bond is defined by the unequal sharing of the electrons between 2 molecules. so if there is a larger difference of electronegativity between 2 molecules, it will be more polar ...

Covalent Bonds: Predicting Bond Polarity and Ionic Character

The polarity of a bond—the extent to which it is polar—is determined largely by the relative electronegativities of the bonded atoms. Electronegativity () was defined as the ability of an atom in a molecule or an ion to attract electrons to itself. Thus there is a

direct correlation between electronegativity and bond polarity.

In a pure covalent bond, the electrons are held on an average exactly halfway between the atoms. In a polar bond, the

electrons have been dragged slightly towards one end. How far does this dragging have to go before the bond counts as ionic?

There is no real answer to that.

What is the difference between the electronegativity and ...

Sodium's electronegativity is 0.9, while chlorine's is 3.0. The difference is 2.1, which is rather high, and so sodium and chlorine form an ionic compound. With 2.1 for hydrogen and 3.5 for oxygen, the electronegativity difference is 1.4. We would expect a very polar bond, but not so polar that the O-H bond is considered ionic.
