Polyimide is one of the most efficient polymers in many industries for its excellent thermal, electrical, mechanical, and chemical properties as well as its easy processability. In the electronic and electrical engineering industries, polyimide has widely been used for decades thanks to its very good dielectric and insulating properties at the high electric field and at high temperatures of around 200°C in long term-service. Moreover, polyimide appears essential for the development of new electronic devices where further considerations such as high power density, integration, higher temperature, thermal conduction management, energy storage, reliability, or flexibility are required in order to sustain the growing global electrical energy consumption. This book gathers interdisciplinary chapters on polyimide in various topics through state-of-the-art and original ongoing research.

Electrical conductivities of sodium-ammonia solutions have been measured from -80 to 185 C, i.e., most of the liquid range and some of the gaseous range. The objective of these studies is the exploration of the possibility of using such gaseous solutions as plasma sources. The attractive features of these gases found in this study include plasma lifetimes in excess of 3,000 seconds (the plasmas being at equilibrium), temperatures as low as 134 C and electrical conductivities of at least 100 mhos/cm. Visual appearances of the dense gases are the same as those of the liquids. Gases with low concentrations of sodium are blue and ones with high concentrations are yellow-red metallic copper gold. Electrical conductivities of the liquids increase with increasing temperature until conductivity maxima are reached at 80 to 100 C. In dilute solutions, the temperatures of these maxima are close to the solution critical tem

peratures; because of this, conductivities of supercritical gases have been measured that are higher than the conductivities of the liquids of the same mole fractions at room temperature. (Author).
