Excerpt from Underground Corrosion From the earth are obtained numerous raw materials that are processed into useful products. Conversely, any product placed in the earth ultimately tends to revert, by deterioration of non metals or corrosion of metals, to their original form as found in nature. As a result, the annual cost to the United States pipeline industry resulting from the protection and replacement of under ground structures due directly to corrosion has been estimated to be in the order of 600 million dollars. In addition, a higher and undeterminable cost results indirectly from corrosion through the loss of products, the loss of life and property by fire and explosion, overdesign of structures, and shutdown of services. This Circular supersedes the National Bureau of Standards Circular 450, issued in 1945, and is a condensed summary of the Bureau's investigations on the corrosion of metals in soils conducted over a period of 45 years. Included are many references to industrial investigations and field experiences related to the Bureau's underground corrosion studies. The aim is to provide a useful reference for the technician who is interested in the theoretical aspects of underground corrosion, and for the engineer who may be interested only in the practical aspects of the methods commonly used for the prevention of corrosion. In interpreting the data reported in the Circular, it should be borne in mind that there are many diverse factors that affect the corrosion of underground structures and that the planning of adequate tests and the proper interpretation of the results are matters of considerable difficulty. Further, much of the subsequently determined phenomena about the causes of corrosion in soils was not generally understood during the organization of the investigations, and many of the early burial programs were exploratory in nature. Hence, for these reasons, experienced engineers frequently have different interpretations for the same corrosion data. Although a complete understanding of the phenomena of underground corrosion has not yet been attained, the results of the National Bureau of Standards investigations, have been a major contribution to a better understanding of the subject. The Craft of Editing William Andrew

Human beings undoubtedly became aware of corrosion just after they made their first metals. These people probably began to control corrosion very soon after that by trying to keep metal away from corrosive environments. "Bring your tools in out of the rain" and "Clean the blood off your sword right after battle" would have been early maxims. Now that the mechanisms of corrosion are better understood, more techniques have been developed to control it. My corrosion experience extends over 10 years in industry and research and over 20 years teaching corrosion courses to university engineering students and industrial consulting. During that time I have developed an approach to corrosion that has successfully trained over 1500 engineers. This book treats corrosion and high-temperature oxidation separately. Corrosion is divided into three groups: (1) chemical dissolution including uniform attack, (2) electrochemical corrosion from either metallurgical or environmental cells, and (3) corrosive-mechanical interactions. It seems more logical to group corrosion according to mechanisms than to arbitrarily separate them into 8 or 20 different types of corrosion as if they were unrelated. University students and industry personnel alike generally are afraid of chemistry and consequently approach corrosion theory very hesitantly. In this text the electrochemical reactions responsible for corrosion are summed up in only five simple half-cell reactions. When these are combined on a polarization diagram, which is explained in detail, the electrochemical processes become obvious.
