To determine optimal cloud-seeding techniques and optimal design specifications for a dry-ice seeding machine (the Cloudbuster), multiple strip seeding of stratiform decks was performed during which seeding rate, pellet size, and strip orientation with respect to wind were systematically changed from strip to strip. Concurrently, the physical properties of the cloud decks were measured and cloud response (i. e., hole size, growth rate, etc.) to the varying treatments was measured photogrammetrically. Results showed that both the dry ice seeding rate and pellet size, as well as the cloud temperature, exerted a strong influence on cloud response. Seeding rate had an optimum of 8-9 lb/naut. mile of CO2 pellets whereafter additional quantities no longer influenced the experiment

predictably. Generally, clouds failed to respond to treatment at 1.8 lb/naut. mile. A minimum recommended quantity of CO2 pellets is 4 lb/naut. mile using a 1 x 1 x 1 cm pellet of 0.5 g/cc density. This CO2 pellet has a fall distance of 1200 ft. When combined with other machine functions, this seeding rate and pellet size allow an output of 10,500 pellets/naut. mile. Cloud response approximately doubles between -5 C and -11 C.A response failure point exists between -3 C and -4 C. Strips should be seeded about 40 min worth of drift upwind of the desired location, and should be seeded across the wind. Seeding altitude for the aircraft should be coincident with the top of the deck for all but thickest decks (> 1200 ft). (Author).
