DNA replication is the copying of DNA so that replicating cells will have enough DNA for daughter cells, or the new cells derived from the original cell. Cell division , or the making of one cell into two new cells, occurs through mitosis for non-sex cells , or those cells not involved in...sex, and meiosis for sex cells , or those

cells that do get down and dirty faster than Vinny and Pauly D on a good night at Karma.

Thus, the old strand of DNA directs the synthesis of a new strand of DNA through complementary base pairing. The old strand then unites with the new strand to re-form a double helix. This process is called semiconservative replication because one of the old strands is conserved in the new DNA double helix. Figure 10-1 DNA replication. The double helix opens and a

complementary strand of DNA is synthesized along each strand.

DNA Replication One of the major misconceptions of DNA replication and cell division is the role of "interphase" in cell replication. Most people think that interphase is this inert "sleeping" phase, and all the exciting activity happens in mitosis. Yet again, it is those mitosis-centric jerks that keep

maligning "interphase."
