Compression ignition occurs when the engine compression is great enough where, if the fuel is injected into the cylinder on the compression stroke, the fuel will spontaneously ignite because of the temperature the air has risen to, due to the compression of the engine. Any gas, including air will get hot when it is compressed.

After a while it became logical to combine the functions of fuel control and ignition into one electronic system known as an engine management system. Engine management Edit. In an Engine Management System (EMS), electronics control fuel delivery, ignition timing and firing order. Primary sensors on the system are engine angle (crank or Top Dead Center (TDC) position), airflow into the engine and throttle demand position.

Compression ignition engine or CI engine is an internal combustion engine in which ignition of the fuel takes place with the help of hot compressed air. As the air is compressed, it gets hot and its heat is used for the ignition and burning of the fuel. In this engine the air is sucked during suction stroke and then this air is compressed while ...

Compression ignition is also commonly referred to as diesel engine, largely because it is a staple of a diesel ignition. Gasoline requires the spark ignition in order to start, but diesel can be started through this alternative means of ignition.

INTRODUCTION TO ENGINE MANAGEMENT SYSTEMS

EMS stands for Engine Management System which consists of a wide range of electronic and electrical components such as sensors, relays, actuators and an Engine Control Unit. Furthermore, they work together to provide the Engine Management System with vital data parameters that are essential for governing various engine functions effectively.

Introduction to Engine Management Systems

Like a gasoline engine, a diesel engine has cylinders, a crankshaft, connecting rods, and pistons to transfer the energy of the fuel from a linear to rotary motion. The primary difference lies in the way they ignite the fuel/air mixture. Gasoline engine are spark ignition engines and diesel-fueled engines are compression ignition engines.

If the ECU has control over the fuel lines, then it is referred to as an electronic engine management system (EEMS). The fuel injection system has the major role to control the engine's fuel supply. The whole mechanism of the EEMS is controlled by a stack of sensors and actuators.

Compression-ignition engines operate more like diesel engines. Diesels are designed for much higher compression (which requires heavier components and stronger construction) and use glow plugs as a heat source rather than spark plugs. Glow plugs heat up the compression chamber, which in turn increases the compression within the chamber.
