Factor analysis is a statistical method used to describe variability among observed, correlated variables in terms of a potentially lower number of unobserved variables called factors. For example, it is possible that variations in six observed variables mainly reflect the variations in two unobserved (underlying) variables.

Books giving further details are listed at the end. As for principal components analysis, factor analysis is a multivariate method used for data reduction purposes. Again, the basic idea is to represent a set of variables by a smaller number of variables. In this case they are called factors.

A brief SAGE publication that provides a lucid introduction to the statistical technique of factor analysis. This is a classic data reduction technique, where one takes numerous variables and then explores the extent to which these can be reduced to a small number of factors underlying the complete complement of variables.

Gorsuch presents a solid introduction to factor analysis. In this, he covers the conceptual basics, including FA's relationship to principal component analysis - a related technique for reducing dimensionality. The presentation includes a few surprises for someone more accustomed to PCA, including non-orthogonal factor and factor rotation.
