Batch Reactor Design Equations  
Conversion (of substance A) is denoted as  $X = \frac{\text{moles of A reacted}}{\text{moles of A fed}}$  - This can be expressed mathematically as  $X_i = \frac{N_{i0} - N_i}{N_{i0}}$   
 $N_{i0} = \sum C_i V_0$   
The number of moles of A in the reactor after a conversion  $X$  has been achieved is  $N_A = N_{A0} (1 - X)$   
By differentiating the above expression with respect to time and plugging it into the expression for the

Guide For Batch Reactor Design

By sizing a chemical reactor we mean we're either determining the reactor volume to achieve a given conversion or determine the conversion that can be achieved in a given reactor type and size.

Here we will assume that we will be given  $-r_A = f(X)$  and  $F_{A0}$ . In chapter 3 we show how to find  $-r_A = f(X)$ . Given  $-r_A$  as a function of conversion,  $-r_A = f(X)$ , one can size any type of reactor.

Batch reactor with single external cooling jacket The single jacket design consists of an outer jacket which surrounds the vessel. Heat transfer fluid flows around

the jacket and is injected at high velocity via nozzles.

The temperature in the jacket is regulated to control heating or cooling.
