Earthquake Engineering and Structural Control: Theory and Applications examines the basics of structural dynamics with its application for earthquake engineering and structural control methods. The objective is not to explain earthquake-resistant design but rather to present different methods of analysis under earthquake and other environmental loads such as fire and physical impact. While presenting fundamental concepts in a simple manner, this book presents structural systems and offshore structures leading to form-dominant design. The response spectrum method and nonlinear time history analysis of structures under earthquake loads are discussed in detail, while the basics of earthquake-resistant design through planning guidelines, as well as introductory seismology, are also covered. Presents dynamic analysis and illustrations of single-degree-of-freedom systems with numerous examples to explain the response spectrum analysis under earthquake and impact loads. Offers detailed solutions to multi-degree-of-freedom systems through numerical methods, supported by MATLAB® examples. Explains the proper application of seismic controls for different classes of structures, including offshore.

This book focuses on gasoline compression ignition (GCI) which offers the prospect of engines with high efficiency and low exhaust emissions at a lower cost. A GCI engine is a compression ignition (CI) engine which is run on gasoline-like fuels (even on low-octane gasoline), making it significantly easier to control particulates and NOx but with high efficiency. The state of the art development to make GCI combustion feasible on practical vehicles is highlighted, e.g., on overcoming problems on cold start, high-pressure rise rates at high loads, transients, and HC and CO emissions. This book will be a useful guide to those in academia and industry.

Production of Biofuels and Numerical Modeling of Chemical Combustion Systems CADCIM Technologies

Turbulent combustion sits at the interface of two important nonlinear, multiscale phenomena: chemistry and turbulence. Its study is extremely timely in view of the need to develop new combustion technologies in order to address challenges associated with climate change, energy source uncertainty, and air pollution. Despite the fact that modeling of turbulent combustion is a subject that has been researched for a number of years, its complexity implies that key issues are still eluding, and a theoretical description that is accurate enough to make turbulent combustion models rigorous and quantitative for industrial use is still lacking. In this book, prominent experts review most of the available approaches in modeling turbulent combustion, with particular focus on the exploding increase in computational resources that has allowed the simulation of increasingly detailed phenomena. The relevant algorithms are presented, the theoretical methods are explained, and various application examples are given. The book is intended for a relatively broad audience, including seasoned researchers and graduate students in engineering, applied mathematics and computational science, engine designers and computational fluid dynamics (CFD) practitioners, scientists at funding agencies, and anyone wishing to understand the state-of-the-art and the future directions of this scientifically challenging and practically important field.
