Metamorphic facies. Metamorphic petrologists studying contact metamorphism early in the 20th century introduced the idea of metamorphic facies (part of a rock or group of rocks that differs from the whole formation) to correlate metamorphic events. The concept was first defined in 1914 by a Finnish petrologist, Pentti Eelis Eskola, as any rock of a metamorphic formation that has attained chemical equilibrium through metamorphism at constant temperature and

pressure conditions, with its ...

Metamorphism and Plate Tectonics. Metamorphic rocks result from the forces active during plate tectonic processes. The collision of plates, subduction, and the sliding of plates along transform faults create differential stress, friction, shearing, compressive stress, folding, faulting, and increased heat flow. The tectonic forces deform and break the rock, creating openings, cracks, faults, breccias, and zones of weakness along which magmas can rise.

Metamorphism, Plate Tectonics, and the Supercontinent Cycle Michael Brown\* Laboratory for Crustal Petrology, Department of Geology, University of Maryland, College Park, MD 20742, USA Abstract:

Granulite facies ultrahigh temperature metamorphism (G-UHTM) is documented in the rock record predominantly from Neoproterozoic to Cambrian; G-UHTM facies series rocks may be inferred at depth in younger, particularly Cenozoic orogenic systems.

Metamorphic Facies Defined and Explained

Metamorphism means change in the rock texture and mineral composition of a rock. Plate tectonics is the scientific theory of large scale plate movements of the earth. Divergent plate margins show greenschist facies metamorphism and the metamorphic rock is metabasalt. Convergent plate margins is a more complex margin including blueschist facies, ophiolite and higher grade of metamorphism including migmatites. Fine grained mylonites and fault breccias dominate in the transform plate margins.

A metamorphic facies is a set of mineral assemblages in metamorphic rocks formed under similar pressures and temperatures. The assemblage is typical of what is formed in conditions corresponding to an area on the two dimensional graph of temperature vs. pressure. Rocks which contain certain minerals can therefore be linked to certain tectonic settings, times and places in the geological history of the area. The boundaries between facies are wide because they are gradational

and approximate. The

### Seven Metamorphic Facies There are seven widely recognized

metamorphic facies, ranging from the zeolite facies at low P and T to eclogite at very high P and T.

Geologists determine a facies in the lab after examining many specimens under the microscope and doing bulk chemistry analyses.

Metamorphic facies is not obvious in a given field specimen.

Metamorphism is the change of minerals or geologic texture (distinct arrangement of minerals) in pre-existing rocks (), without the protolith melting into liquid magma (a solid-state change). The change occurs primarily due to heat, pressure, and the introduction of chemically active fluids. The chemical components and crystal structures of the minerals making up the rock may change even

The movement of tectonic plates transports sediment and rocks into different geologic setting—these changes can result in metamorphism, particularly in zones where tectonic plates are converging, as in a subduction zone or where continental plates converge, pushing up high mountain ranges while material below the mountains are pushed down under increasing temperature and pressure condition.

rocks, and is associated with tectonic processes such as plate collision and crustal thickening (orogenic metamorphism) and ocean-floor spreading (ocean-floor metamorphism).
