Excerpt from *The Design of Marine Engines and Auxiliaries* The production of a book upon marine engine design must necessarily involve the use of material from many sources. It is so difficult to determine the ultimate source of all till material that the author has not attempted the task. It is far easier to point out those portions of the book which have some degree of originality and then to make a general acknowledgment of indebtedness for the remainder. So far as the author knows the following methods are original: the method of design (§§ 13 to 22), the method of obtaining mean bearing loads (§§ 86 to 90), the use of the mean lead in the solution of valve diagrams (§ 105), the method of designing condensers (§ 156), the method of designing turning engines (§§ 173 to 177). In the section on Engine Balancing, although no portion of the material is original, much time and effort has been expended in correlating the work of various investigators. The question of pressures upon main bearings will be found more extensively treated in a paper by the author in Vol. 18, Part I, of *The Journal of the American Society of Naval Engineers*. The author wishes to acknowledge the kindness of the Newport News Shipbuilding and Dry Dock Company in permitting him to use certain drawings for Plates 1, 2, and 3. Excerpt from *Modern American Marine Engines, Boilers and Screw Propellers: Their Design and Construction, Showing the Present Practice of the Most Eminent Engineers and Marine Engine Builders in the United States, Among Others, Charles W. Copeland, Charles E. Emery, Robert H. Thurston, Thomas Main, Thomas Jackson* This work is presented to the Marine Engineers of the United States by one of their number, who hopes and believes it will be found a valuable and most useful companion in their daily labors. These examples of Modern American Marine Engines and Boilers are the work of the master-minds of the profession (contributed by themselves especially for this work), and are given to the student for his careful study and consideration, just as the works of the old masters are placed before the young art student, to be copied if necessary, or improved upon if his genius will permit it. The object and aim of this work is to enable the student to place himself abreast of the best and most successful practice of the present day in the design and construction of the latest and most improved marine engines and boilers; or, in other words, the purpose is to impart, with all necessary fullness, that special information as regards new methods of design and construction, which every engineer desires to obtain, but which at present is almost inaccessible. Marine Engines Performance and Emissions Forgotten Books

The international marine shipping industry is responsible for the transport of around 90% of the total world trade. Low-speed two-stroke diesel engines usually propel the largest trading ships. This engine type choice is mainly motivated by its high fuel efficiency and the capacity to burn cheap low-quality fuels. To reduce the marine freight impact on the environment, the International Maritime Organization

(IMO) has introduced stricter limits on the engine pollutant emissions. One of these new restrictions, named Tier III, sets the maximum NOx emissions permitted. New emission reduction technologies have to be developed to fulfill the Tier III limits on two-stroke engines since adjusting the engine combustion alone is not sufficient. There are several promising technologies to achieve the required NOx reductions, Exhaust Gas Recirculation (EGR) is one of them. For automotive applications, EGR is a mature technology, and many of the research findings can be used directly in marine applications. However, there are some differences in marine two-stroke engines, which require further development to apply and control EGR. The number of available engines for testing EGR controllers on ships and test beds is low due to the recent introduction of EGR. Hence, engine simulation models are a good alternative for developing controllers, and many different engine loading scenarios can be simulated without the high costs of running real engine tests. The primary focus of this thesis is the development and validation of models for two-stroke marine engines with EGR. The modeling follows a Mean Value Engine Model (MVEM) approach, which has a low computational complexity and permits faster than real-time simulations suitable for controller testing. A parameterization process that deals with the low measurement data availability, compared to the available data on automotive engines, is also investigated and described. As a result, the proposed model is parameterized to two different two-stroke engines showing a good agreement with the measurements in both stationary and dynamic conditions. Several engine components have been developed. One of these is a new analytic in-cylinder pressure model that captures the influence of the injection and exhaust valve timings without increasing the simulation time. A new compressor model that can extrapolate to low speeds and pressure ratios in a physically sound way is also described. This compressor model is a requirement to be able to simulate low engine loads. Moreover, a novel parameterization algorithm is shown to handle well the model nonlinearities and to obtain a good model agreement with a large number of tested compressor maps. Furthermore, the engine model is complemented with dynamic models for ship and propeller to be able to simulate transient sailing scenarios, where good EGR controller performance is crucial. The model is used to identify the low load area as the most challenging for the controller performance, due to the slower engine air path dynamics. Further low load simulations indicate that sensor bias can be problematic and lead to an undesired black smoke formation, while errors in the parameters of the controller flow estimators are not as critical. This result is valuable because for a newly built engine a proper sensor setup is more straightforward to verify than to get the right parameters for the flow estimators.

Excerpt from Marine Engine Design: Including the Design of Turning and Reversing Engines It was not the idea in this work to cover in detail the design of every part of the engine, but enough is given in the way of detailed design of the principal parts to indicate the general scope of the problem and to lay down methods by which the entire work can be carried to completion. As given, this represents the results of several years of experience in teaching the subject of marine engine design to students of the University of Michigan. This third, revised edition of Stan Grayson's classic history and appreciation of early gasoline marine engines contains several new appendixes, and an expanded list of U.S. and Canadian marine-engine builders -- 750 of them. Among several new chapters, there is a discussion of engine collecting and use that includes tips on propellers and matching engines and boats. This book is much more than lists and nuts and bolts, however. It is fascinating social history, an astute study of how these machines were created, tinkered with, used, cursed, and most recently collected -- and how they changed the small-boat world at the beginning of the twentieth century.
