Modern Control Engineering focuses on the methodologies, principles, approaches, and technologies employed in modern control engineering, including dynamic programming, boundary iterations, and linear state equations. The publication first ponders on state representation of dynamical systems and finite dimensional optimization. Discussions focus on optimal control of dynamical discrete-time systems, parameterization of dynamical control problems, conjugate direction methods, convexity and sufficiency, linear state equations, transition matrix, and stability of discrete-time linear systems. The text then tackles infinite dimensional optimization, including computations with inequality constraints, gradient method in function space, quasilinearization, computation of optimal control-direct and indirect methods, and boundary iterations. The book takes a look at dynamic programming and introductory stochastic estimation and control. Topics include deterministic multivariable observers, stochastic feedback control, stochastic linear-quadratic control problem, general calculation of optimal control by dynamic programming, and results for linear multivariable digital control systems. The publication is a dependable reference material for engineers and researchers wanting to explore modern control engineering.

They begin with state space tools for analysis and design, including stability of solutions, Lyapunov functions, reachability, state feedback observability, and estimators. The matrix exponential plays a central role in the analysis of linear control systems, allowing a concise development of many of the key concepts for this class of models. Åström and Murray then develop and explain tools in the frequency domain, including transfer functions, Nyquist analysis, PID control, frequency domain design, and robustness. Features a new chapter on design principles and tools, illustrating the types of problems that can be solved using feedback Includes a new chapter on fundamental limits and new material on the Routh-Hurwitz criterion and root locus plots Provides exercises at the end of every chapter Comes with an electronic solutions manual An ideal textbook for undergraduate and graduate students Indispensable for researchers seeking a self-contained resource on control theory

This course provides an overview of the major techniques of "modern" control theory. Although control systems have existed for many years, development of the formal scientific theory did not begin until the 1940s. During the late 1960s and since, new approaches to control problems have developed. Unfortunately modern techniques are so complex that each has a specialized literature with only incidental reference to others. The goal of this course is to provide a broad picture of all of the major modern control techniques which are likely to be used in practical control systems. Students who complete this course will understand similarities and differences between the methods and will be able to identify the most appropriate approach for any given application. Each lesson is self-contained and includes the following elements: brief introduction and expected outcomes, lesson material with closing summary, glossary and examples, examination questions with answers and solutions, references. Course includes: study guide, workbook and final exam. You will earn 8 Continuing Education Units (CEUs) upon successful completion.
