## Ninth grade Lesson Interior and Exterior Angle Sum of Polygons

The word "polygon" means "many angles," though most people seem to notice the sides more than they notice the angles, so they created words like "quadrilateral," which means "four sides." Regular polygons have as many interior angles as they have sides, so the triangle has three sides and three interior angles. Square? Four of each. Pentagon? Geometry Practice Problems with Triangles and Polygons ...

- How to determine the central angle measure of a regular polygon.
- The relationship between the sum of the interior angles of a triangle and the sum of the interior angles of a regular and irregular

polygon. • How to apply geometric representations of the expressions  $(n - 2)180$  and  $180 \cdot n - 360$  to Interior Angles of Polygons

You can see that the interior angle and exterior angle are supplementary, adding to  $180^\circ$ . As you drag the vertex downwards the polygon becomes concave, with the vertex pushed inwards towards the center of the polygon. As this happens the extended side now moves inside the polygon and the exterior angle becomes negative.

For a regular polygon with 10,000 sides (a myriagon) the internal angle is  $179.964^\circ$ . As the number of sides increase, the internal angle can come very close to  $180^\circ$ , and the shape of the polygon approaches that of a circle.

### Regular Polygons And Angle Relationships

If you're asking for an expression for the angles in a regular polygon, then here you are: If you walk along the edge, all the way around, you will have turned a total of  $360^\circ$ , so in each corner, you turn  $\frac{360^\circ}{n}$ . The internal angle is the supplementary angle of this, and is therefore  $180 - \frac{360}{n}$ . [geometry - Dependence of internal angles on the number of ...](#)

The sum of the measures of the interior angles of a polygon with  $n$  sides is  $(n - 2)180$ . The measure of each interior angle of an equiangular  $n$ -gon is If you count one exterior angle at each vertex, the sum of the measures of the exterior

angles of a polygon is always  $360^\circ$ .

Geometry – Angles of Polygons

Then, we define "regular" as a polygon having all equal sides, and wrap up by learning about the sum of all EXTERIOR angles of any polygon. That sum of all exterior angles is always 360 degrees.

The radius of the incircle is the apothem of the polygon. (Not all polygons have those properties, but triangles and regular polygons do).

Breaking into Triangles. We can learn a lot about regular polygons by breaking them into triangles like this: Notice that: the "base" of the triangle is one side of the polygon.
