The Stirling Cycle The key principle of a Stirling engine is that a fixed amount of a gas is sealed inside the engine. The Stirling cycle involves a series of events that change the pressure of the gas inside the engine, causing it to do work. There are several properties of gasses that are critical to the operation of Stirling engines:

A Stirling engine is a heat engine operating by cyclic compression and expansion of air or other gas, the "working fluid", at different temperature levels such that there is a net conversion of heat to mechanical work.

In a common design called a two-piston (or alpha) Stirling engine, there are two identical pistons and cylinders and the gas shuttles back and forth between them, heating and expanding, then cooling and compressing, before the cycle repeats.

The Stirling Engine must be fueled with Saplings, Coal, Wood, or a Lava Bucket and it must be activated with a Redstone signal. It can be used to power a variety of machines such as the Mining Well. It can be connected to other Stirling Engines to add power, or can be connected to a Kinesis Pipe to transport that power elsewhere.

Stirling engines feature a completely closed system in which the working gas (usually air but sometimes helium or hydrogen) is alternately heated and cooled by shifting the gas to different temperature locations within the system. In the two-cylinder (or alpha configured 3) Stirling, one cylinder is kept hot

while the other is kept cool.

Stirling engines (formerly referred to as steam engines) are the second tier of engine. They use cobblestone instead of wood or iron so are still cheaper than the Combustion Engine. Previously, it had been stated that Stirling Engines would not blow up and would simply stop operating when heated too much.

A Short Explanation of Stirling Engines A fixed amount of gas is sealed inside an engine. The gas is then moved back and forth from the hot side to the cold side of the engine. When the gas is on the hot side, it is heated and expands.
