Since the spring rate of the torsion bar stays as good as the same whatever height you set it at; you can simply reduce the idle damper measurement by 1/3rds the amount you want to lower the car, and refit the torsion bars there and a new ride height is set. The adjustment of the torsion bars isn't quite infinite, but about 3mm increments.

One end of a long metal bar is attached firmly to the vehicle chassis; the opposite end terminates in a lever, the torsion key, mounted

perpendicular to the bar, that is attached to a suspension arm, a spindle, or the axle. Vertical motion of the wheel causes the bar to twist around its axis and is resisted by the bar's torsion resistance.

Turn the torsion bar bolt counterclockwise to lower the vehicle. Slide under your raised vehicle while holding a ratchet wrench with a socket attached. Place the socket over the torsion bolt, twisting the

tool in a counter-clockwise direction. Twist the wrench in 180-degree increments if you're unable to make a full rotation.

Lowering the beam means removal of the torsion bars or, at the very least, removal of one end and the trailing arm repositioned. It is this initial part of removing the arm from the torsion bar that causes so much horror in the minds of the virgin beam re-builder.

Removed the torsion bars

completely, adjusted the lower wishbones to 47.00 cm instead of 46.3, rotated the torsion on each side for about 30 trials and figured out what the best position is of all. The bars went in on both side by hand for have the distance and the rest was done with some hits on the back.
