Ultrasound has revolutionized the practice of regional anesthesia, yet there

remains a paucity of good resources on ultrasound-guided regional anesthesia in children. This book offers a much-needed practical guide to all the major ultrasound-guided blocks in pediatric patients, including neuraxial, truncal, upper and lower limb blocks.

A deep detailed knowledge of the pudendal nerve anatomy and its variants is essential for the use of imaging-guided regional anaesthesia techniques. Ultrasound has shown to be of great help in nerve localisation in order to guide and control the application of anaesthetic or analgesic mixes in a more accurate, safe and efficient way.

A growing body of medical research supports the use of ultrasound guidance for regional anesthesia. For example, with ultrasound guidance compared to peripheral nerve stimulation, there was shown to be a significant decrease in the risk of vascular puncture (risk ratio of .16); an increase in the nerve block duration by 25%; and a 29% faster onset time 1.

Ultrasound guidance is rapidly becoming the gold standard for regional anaesthesia. There is an ever growing weight of evidence, matched with improving technology, to show that the use of ultrasound has significant benefits over conventional techniques, such as nerve stimulation and loss of resistance.

To be successful at ultrasound-guided neural blockade, one must be familiar with the relevant cross-sectional anatomy and the coordination of the imaging probe with the block needle.

Ultrasound has many roles in pain management interventions, both peripheral and neuraxial.

Ultrasound Guided Regional Anaesthesia

"Most people need two things to climb the learning curve of ultrasound-guided regional anesthesia (UGRA): (1) tons of repetition in high fidelity simulation and (2) immediate feedback from experts. Most UGRA

courses offer feedback from experts, but Maverick is the only company with pulsatile cadavers for their simulation.

Introduction to Ultrasound-Guided Regional

Anesthesia - NYSORA

Ultrasound equipment and settings for regional anaesthesia Either a laptop-or a cart-based machine is applicable. The most commonly used probe is a high-frequency, linear array probe (5–10 MHz), as this gives good spatial resolution for the nerves and plexuses, which are usually superficial (1–5 cm deep).

Ultrasound for Regional Anesthesia

Ultrasound-guided regional

anesthesia (UGRA) is difficult to learn and takes many years to attain expertise. Anesthetic trainees lack confidence, 1 find interpretation of ultrasound challenging, 2 display wide variability in UGRA performance, 3 and may expose patients to repeated attempts, pain, and harm. 4 In a study scanning volunteers' axillae, trainees committed three times more errors ...
